# Impact of migration/proliferation plasticity on tumor development

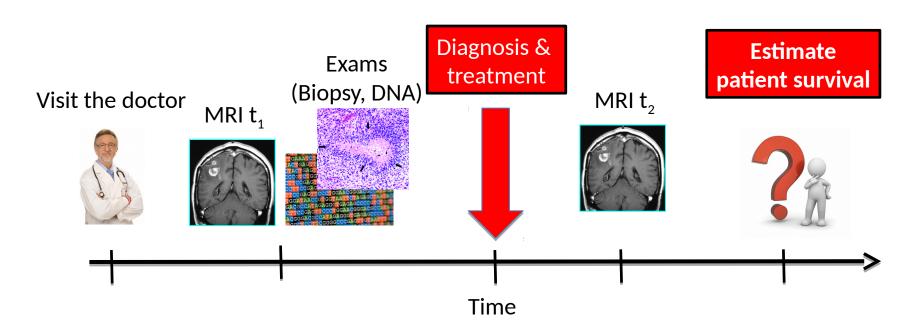

### H. Hatzikirou

# Cancer in clinics

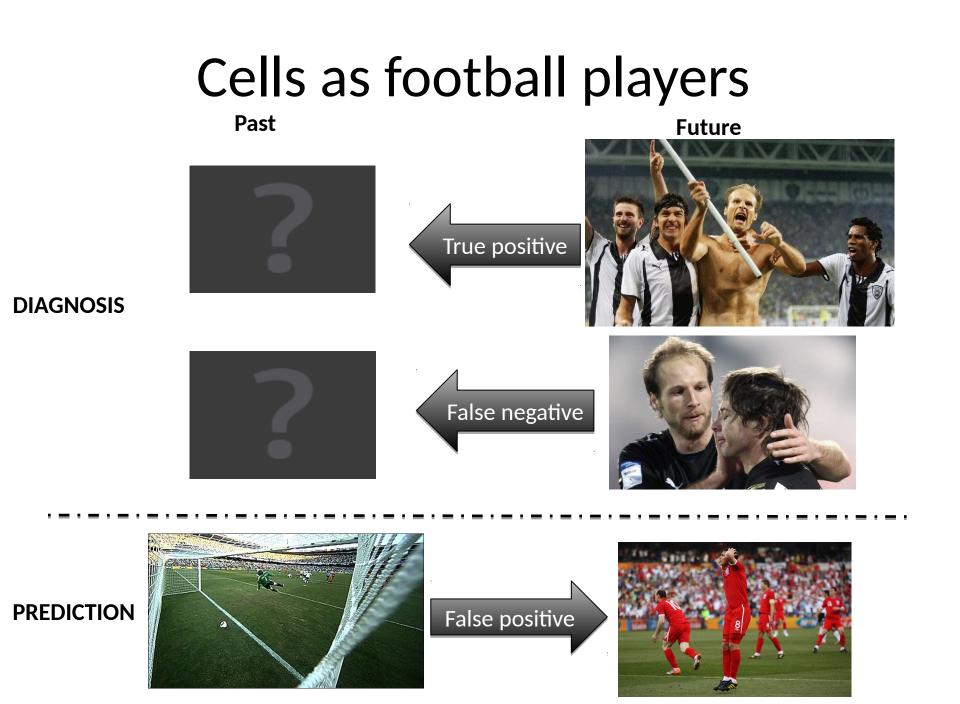

Fact: Sparse data in time.

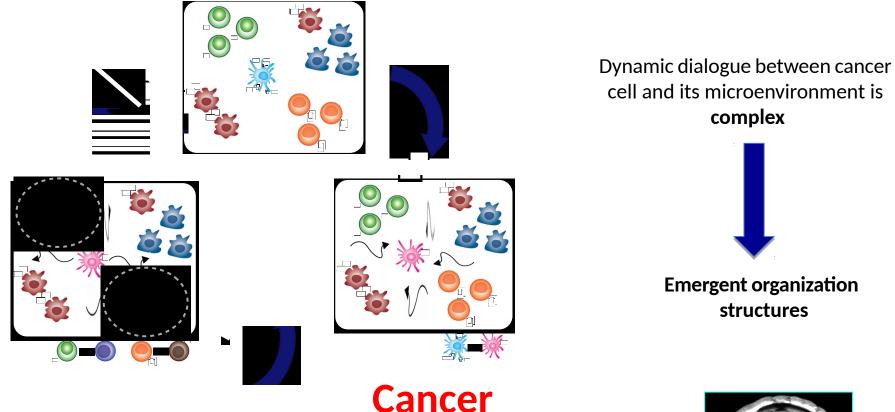

**Diagnosis**: Select treatment upon lesion's **past** 

Survival: Predict the future

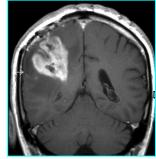

**Problem**: Restricted mechanistic understanding of causalities

## Cancer cell decision-making

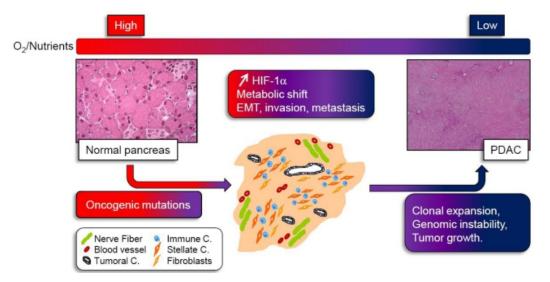

"Cancer is no more a disease of cells than a traffic jam is a disease of cars. A lifetime of study of the internal-combustion engine would not help anyone understand our traffic problems. " - D. W. Smithers (1962)

## Phenotypic plasticity

**Phenotypic plasticity** := ability of a cell to **reversibly decide** over its phenotype in response to changes in the micro-environment

- Epithelial-Mesenchymal Transition
- Shift to anaerobic, glycolytic metabolism (Warburg effect)

Vaes ur S, Tomaisni R, Tournaire R, Iovanna LJ . Hypoxia induced tumor metabolic ws itch contributes to pancreatic cancer aggreiss veness Cancers 2010; 2(4):2138-52.

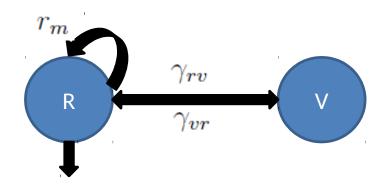

# Phenotypic plasticity: "Go or Grow"

Tumor cells (*glioma*) employ a particular **decision mechanism** depending on local information (resources):

"Go or Grow" or migration/proliferation dichotomy

### PAY-OFF

More proliferation, less migration and vice versa

## The menu

- 1. Can we identify the "Go or Grow" mechanism and its functional dependencies from experimental set-ups?
- 2. How "Go or Grow" influences glioma tumor initiation and persistence?

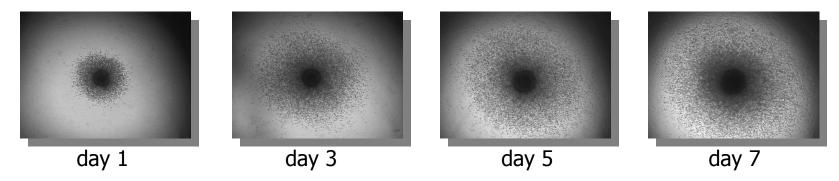

## **1. Identification**

### Experimental data

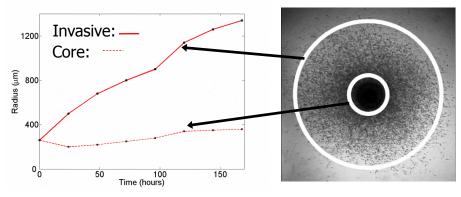

Multicellular glioma spheroids are implanted in collagen gel and grow for 7 days

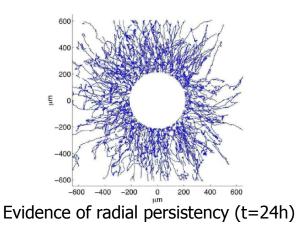

Cells are shed from the spheroid and invade the collagen

- **Observations:** The core and invasive radii expand with different speeds
  - At early stages of the experiment, cells move away from the core with high radial persistency

Time evolution of the core and invasive radii

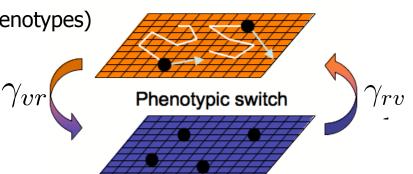

### The model

### Lattice Gas Cellular Automaton

**Dynamics: Control model** 

**State space:** Two glioma cell populations (phenotypes)

resting and moving

Lattice for moving cells

Lattice for resting cells  $r_m$ : proliferation rate

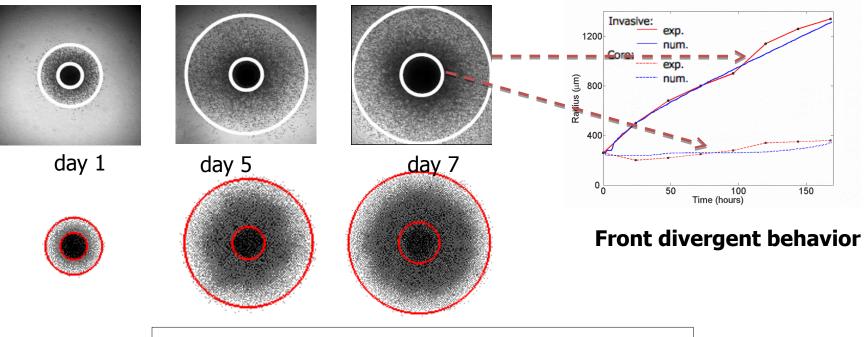

Dynamics/Rules	CA Rules	$r_m$
Proliferation	both populations	$\begin{array}{c c} & \gamma_{rv} \\ \hline \\ R & \gamma_{rv} \end{array}$
Motion	random walk	$\gamma_{vr}$
Phenotypic switch	constant rate

# Identification

M. Tektonidis, H. **Hatzikirou**, A. Chauviere, M. Simon, A. Deutsch Identification of intrinsic cellular mechanisms for glioma tumor invasion. JTB, 2011

Multicellular glioma spheroids are implanted in collagen gel and grow for 7 days
 Cells are shed from the spheroid and invade the collagen *Stein et al.*, Biophysical Journal (2007)

What are the responsible mechanisms?

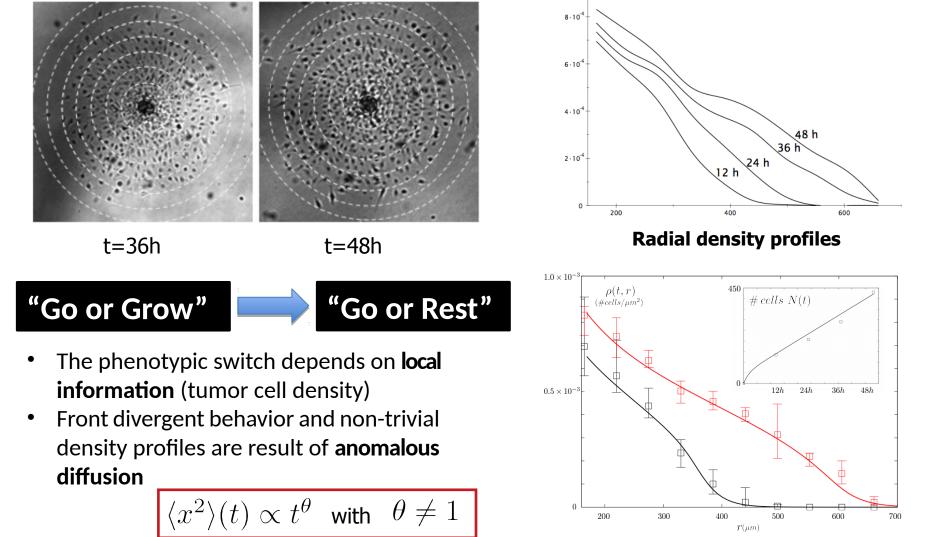

Go or Grow depends on local cell density © .. but exact density dependency is not conclusive 🛞

# Verification

2D experimental data (no proliferation)

(a) cell reactions

(b) cell propagation

# Mean-field analysis

**Assumption 1:** Mean-field assumption  $E[N_t^2] = E[N_t]^2$ **Assumption 2:** Switching dynamics are faster than cell migration and proliferation

Mean-field equation:

$$\partial_t \rho = \partial_x \left( D(\rho) \partial_x \rho \right) + F(\rho)$$

Reaction term:

$$F(\rho) = R_b r_s(\rho) \rho \left(1 - \rho\right) - R_d \rho$$

$$r_s(\varrho) = \frac{1}{2}(1 + \tanh(\kappa(\varrho - \theta))), \quad \varrho \in [0, 1].$$
 Switching function

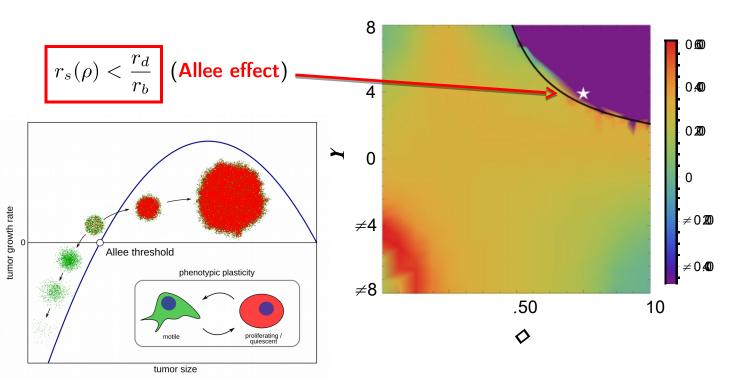

**Diffusion term:** 

rm: 
$$D(\rho) = D\left(\frac{1 - r_s(0)}{2} - r'_s(0)\rho - \frac{3}{2}r''_s(0)\rho^2\right), \quad \rho \ll 1$$

The system exhibits **bistability** for  $\rho$ =0 and  $\rho$ = $\rho^*$  <1: (i) Adhesive case  $\kappa > 0$ (ii)  $r_s(\varrho)r_b < r_d$ 

## **Emergent population dynamics**

Total population gor two har te of the er sting cell population depends on the phenotypic six tch par meter  $\kappa \sigma a$ .

The representation of the representation of

## **Critical behavior**

### Extinction

### Growth

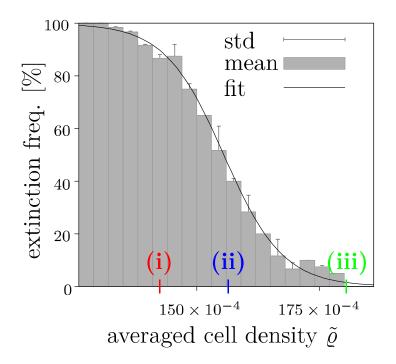

#### Identical initial condition and parameters for both simulations

## **Extinction of small tumors**

0.06

Stochastic fluctuations lead to extinction or growth given a fixed small initial condition.

$$\tilde{\varrho} = |\mathcal{L}|^{-1} \sum_{\mathbf{r} \in \mathcal{L}} \varrho(\mathbf{r})$$

Low-density initial populations in the critical regime show bimodal stationary size distribution, indicating the possibility of either population extinction or persistence.

## And what about real tumors?

**Fact**: Low-grade cell line cultures, *in vivo* and *in vitro*, have low chances of persistence and low reproducibility.

On the contrary, tumor establishment in high-grade cell lines is repeatedly observed. [Huszthy et al. Neuro Oncol 2012; Tilkorn et al. Anticancer Res 2011]

**Potential explanation**: Allee effect for low grade tumors. Tumor initiation depends on stochastic fluctuations and initial cell density.

#### **Conjecture on tumor progression:**

The sign of parameter **k** defines tumor malignancy (ongoing work)

WHO grade	cellular density	mitotic activity	spread	others
II	low	no/rare	low ( diffuse infiltrative)	
III	increased	high	medium	nuclear polymorphism
IV	high	brisk	high (widely infiltrative)	cellular and nuclear anaplasia, microvascular proliferation, necrosis, vascular thrombosis

# Ευχαριστώ!
